PLANESYSTEM®

Function meets esthetics
WHEN IT COMES TO HEALING …

... only the best is good enough. For this reason, we decided to work with my long-time colleague, Udo Plaster, MDT, in the realm of patient and model analysis.

His PlaneSystem® is a transfer method that respects and recognizes the patient as a person. Whether we choose the digital or the traditional route in the preparation of dental restorations, the accurate recording of patient data by the PlaneSystem® will pave the way for the pursuit of complete health. Our company’s software developers have integrated the PlaneSystem® into the Zirkonzahn CAD/CAM workflow. We have pledged our knowledge and our competence, as well as our organizational structures and international presence, in support of the PlaneSystem®.

So on the path towards a complete digital acquisition of the facial position on the articulator, Zirkonzahn, with its Face Hunter 3D facial scanner, developed in-house, and the PlaneSystem®, has taken two major hurdles and enjoys the infinite benefits that hard work and human effort can produce.

We encourage you to join us in aspiring to more, in being open to new developments and curious for new in-depth knowledge!

PlaneSystem® – developed by Udo Plaster MDT in cooperation with Zirkonzahn
Dental technicians need very precise data about each patient’s individual situation to develop restorations in a virtual environment. The more precise the data, the better the achievable function and esthetics of design (Fig. 1). In some situations, however, the technician will be unable to exploit the full potential of CAD planning software. This case may arise in the absence of information on how an available pair of casts relates to the rest of the body.

**OCCLUSAL PLANE AND MIDLINE**

The precise position of the human maxilla, which forms an integral part of the skull, varies from individual to individual, depending on skeletal growth types, and the orientation of the occlusal plane is dictated by the growth pattern of the maxilla and mandible. For example, less growth of the mandible relative to the maxilla will normally involve an increasingly steeper orientation of the natural occlusal plane (Fig. 2). Differences in occlusal plane inclination may even be present within an individual (due to natural bone volume asymmetries on both sides of the face) and can be verified based on the ala tragus line (Fig. 3). The absolute midline of the face is another suitable reference to identify natural asymmetries of the dental arch. This vertical line passes through the nasion (point between the eyebrows) and the subnasal point (point below the nasal tip). Normally, it will coincide with the skeletal midline that runs along the palatal suture. The dental midline, by contrast, will normally depart from the absolute midline by varying degrees to the left or right (Fig. 4). It is generally assumed that no human skull ever grows to ideal symmetry. The fact that the stomatognathic system is nevertheless capable of accomplishing its function results from the body’s ability to offer some compensation for asymmetries through its muscles. Over time, this fundamental asymmetry can be compounded by additional asymmetries developing in the jaws because of tooth loss, reduced vertical

Fig. 1: Ideal situation characterized by a 1:1 transfer of the maxillary position in the skull to the articulator and into the CAD software

Fig. 2: Skeletal growth types with different orientations of the occlusal plane

Fig. 4: Fundamental asymmetry developing in the jaws because of tooth loss, reduced vertical
Fig. 4: The midlines and the skeletal midlines form the absolute midline. The dental midline is not normally located along this line.

Dental restorations may also be a cause of asymmetric loads inside the body. These may be avoided, however, if the clinician succeeds in identifying the position of the maxilla within the skull and determining how any asymmetries that may be present relate to this position. But what options are there available for the clinician to achieve this goal?

FACEBOWS AND TRANSFER BOWS

Conventional facebows and transfer bows have traditionally yielded good results in fabricating dental restorations. Experience tells us, however, that numerous try-ins and adjustments are normally required before a patient will be satisfied with the functional design of his or her dental restoration. This need arises from incomplete information about the maxilla, as familiar measuring techniques do not use reference points...
and reference planes suitable to record the position of the maxilla in the skull directly from the patient for subsequent transfer to the articulator. Yet data about the position of the maxilla are essential to identify the patient’s midline and occlusal plane for consideration in fabricating the dental restoration. The technician needs both of these parameters to appropriately position the dental reconstruction inside the jawbone, thus closely imitating the natural ideal situation and avoiding the development of asymmetric loads inside the body.

THE PLANESYSTEM®

This system offers an alternative to conventional facebows in this regard. The name PlaneSystem® was selected to reflect the crucial role of the planes that the system identifies in the patient’s skull, including the absolute midline, the zero-degree reference plane, and the individual occlusal plane (captured via the zero-degree reference plane). Also, the name refers not only to the measuring and transfer method per se, but also to the specifically developed equipment and the associated software by Zirkonzahn. The system comprises four elements:
PlaneFinder® (Fig. 5), PlanePositioner® (Fig. 6), the PS1 laboratory articulator (Fig. 7), and the CAD-PlaneTool PS1-3D (Fig. 8).

Using the PlaneSystem®, it becomes possible to capture the position of the maxilla in the skull and the occlusal plane in almost any individual. This may include cases of dentate, edentulous or prosthetically restored maxillae, as well as situations characterized by loss of dental hard tissue, bite position, or single or multiple teeth. At the source of this process is one of the numerous amazing properties of the human body. All humans, when looking into a mirror, whether sitting down or standing on both legs in a stable position, will invariably, by engaging all natural aids (eyes, neck muscles, equilibrium organ), adjust their orientation such that the head posture will intuitively be in balance with the body position and the sight axis parallel to the horizon.

This position is almost identically reproducible at all times, offering a stable frame of reference for the PlaneSystem® to record the position of each patient’s maxilla in the skull and to measure his or her occlusal plane and related facial asymmetries. The same position is also known as Natural Head Position (NHP).

**MEASURING AND RECORDING**

Recording the position of the maxilla and measuring the occlusal plane starts out by placing the PlaneFinder® on a level surface and aligning its upper arm horizontally. The extension of the arm thus provides a zero-degree reference plane, horizontally hemisecting the face at a zero-degree angle relative to the floor or base surface once the patient has placed his or her head in NHP (Fig. 9). That this zero-degree angle can be revisited any time – because the NHP is reproducible – renders the reference plane independ-
ent of any physical asymmetries. An independent reference value of this type could not be ensured by using a conventional facebow, which would involve application of a symmetrical measuring instrument to the asymmetric skull while there is no way for the articulator to reflect these asymmetries.

To record the position of the maxilla in the NHP, the maxilla is placed by the patient upon a bite tray connected to the PlaneFinder®, followed by indexing of this position with bite registration material (Fig. 10). The fact that the patient will always be able to return to this position in which the reference plane has been measured, guarantees the independent nature of this plane now recorded in a silicone index. The same applies to the inclination of the occlusal plane. Again, the zero-degree reference plane identified by the PlaneFinder® serves as an independent reference plane, which can be reproduced based on the patient’s NHP at any time. The inclination angle is determined based on the ala tragus line, whose orientation may be assumed to be parallel to the natural occlusal plane (Figs. 11 and 12). This line extends from the lower border of the nasal wing (ala nasi) to the cartilage before the opening of the ear (tragus). As the bilateral values for this
Fig. 12: ... may have an ascending, horizontal or descending inclination
inclination may vary due to natural asymmetries, its angle is measured on both sides of the face.

TRANSFER TO THE ARTICULATOR

The next step is to insert the maxillary cast into the silicone index, followed by placing the index onto the (horizontally oriented) PlanePositioner® and positioning inside the PS1 articulator, effectively “copying” the situation recorded directly from the patient to the articulator (Fig. 13). After fixing the cast, the silicone index can be removed and the inclination of the occlusal plane can now be replicated by adjusting the PlanePositioner® inside the articulator to the angle values previously identified via the PlaneFinder® (Fig. 14).

From this point in developing the patient case, it will be possible to recheck the occlusal plane whenever the need arises on the PS1 articulator. For example, Fig. 15 shows a mounted edentulous maxilla with a temporary restoration, which was repeatedly checked to see whether the occlusal plane designed at different points during the development of the case coincided with the natural occlusal plane that had been recorded directly from the patient.
POSSIBILITIES IN THE SOFTWARE

In the Zirkonzahn.Scan software environment, a project is created using the CAD-PlaneTool PSI-3D, followed by digitization of the mounted cast with the Zirkonzahn S600 ARTI scanner (Fig. 16). Data which can be stored in this context include the patient’s absolute midline (Fig. 17), the occlusal plane (Fig. 18), tooth proportions as well as various 2D/3D photographic images (Face Hunter) and cephalograms (Figs. 19 and 20). For a well-founded esthetic matching of the restorative tooth shapes and positions with the shape and gestures of the face, the patient should be depicted in those photographs from different angles.
angles and with varying facial expressions (like serious or laughing or smiling).

The next step is to open the project in the Zirkonzahn.Modellier environment. This will make more information (in addition to the photographs) available for the virtual design process, including the position and inclination of the natural occlusal plane in relation to the current position of the maxilla, whereby the dental restoration can now be related to the natural occlusal plane also in the digital domain (Figs. 21 and 22), as well as the position of the absolute midline in relation to the current position of the maxilla, which may be used as reference for positioning the dental midline (e. g. in edentulous maxillae) to avoid asymmetric loads inside the body (Fig. 23). Starting from the absolute midline, the remaining tooth reconstructions are positioned in their correct proportions with the help of median values. (Fig. 24).
CONCLUSION

Thanks to a fluid and smart workflow, all measurements, records and the articulation carried out by means of the PlaneSystem® can be used in further steps of the case realization. The PlaneSystem®’s hardware and software elements used in this process are designed to include both function and esthetics in the realization of dental restorations.

While exact recording and measuring of each patient’s situation will reduce the time for refinements needed to adjust the restoration to the individual requirements, this will not, of course, eliminate the need for direct try-ins in the patient’s mouth to check his or her facial expressions (soft-tissue support), esthetics, phonetics, and function.

Yet by taking into consideration the natural inclination of the occlusal plane on both sides of the dental arch, it should be possible to come very close to achieving the requirements that the dental restoration should meet in the patient’s mouth even before the first try-in. Everybody involved can save valuable time in this way.

The occlusal plane of the restoration can be repeatedly checked, as needed, for agreement with the natural occlusal plane, both in the digital domain using the software and in the physical domain using the PSI articulator. This is a key benefit of the system, considering that even subsequent adjustments to restorations will not always succeed in compensating for a poorly simulated occlusal plane.

OCCLUSALLY SCREW-RETAINED PRETTAU® BRIDGES ON SIX MAXILLARY TITANIUM BASES AND FOUR MANDIBULAR IMPLANTS WITH A TITANIUM BAR

The patient situation was scanned by Udo Plaster, MDT, using the PlaneSystem® and replicated in an articulator. The first trial set-ups were sent, along with the casts, to the Dental Laboratory Steger to be implemented and scanned. The try-ins were used as the diagnostic cast, and a titanium bar was designed as a reinforcement for the extended cantilevers in the mandible. The titanium bar was milled in the M1 milling unit, refined with a parallelogram and high gloss-polished. After re-scanning the bar, the superstructure was adjusted based on the new situation and modelled. The maxilla, too, was designed according to the situation and the occlusion was then tested against the mandibular situation. The work was then milled in Prettau® Zirconia and finished. Cutbacks were made in the anterior region and in the gingival areas. The two Prettau® Bridges were coloured, dried and sintered in the Zirkonofen 700 Ultra-Vakuum. Then the restorations were re-fitted on the model, and the occlusion was adjusted by removing premature contacts. The cutback areas on the vestibular surfaces of the anterior teeth and the gingival area were veneered with ICE Zirkon Ceramics. The final characterisation was carried out by applying ICE Zirkon 3D Stains by Enrico Steger and glazing.

COMPLETE MAXILLARY AND MANDIBULAR REHABILITATION USING PRETTAU® ZIRCONIA

A patient case of edentulous maxilla and mandible, with 6 implants in the upper jaw and 4 in the lower jaw, was the basic situation of the described restoration. In the first phase of the treatment, we acquired the Natural Head Position (NHP) and all the necessary facial data through the PlaneSystem® and the Face Hunter and imported them into the software. Based on the digital data, we mounted the models in the virtual articulator and subsequently designed the restoration. We then produced provisional bridges made from resin. At this point, using the JawPositioner, we transferred the virtually articulated model of the maxilla 1:1 into the laboratory articulator. After two months of intraoral functioning, the provisional bridges were removed from patient’s mouth, checked and scanned in order to incorporate any possible changes into the final zirconia reconstruction. Since no changes were applied, we directly modeled the final restoration. We chose Prettau® Zirconia for the material because of its long-lasting durability and high esthetic qualities. The two structures were milled in the M4 Wet Heavy Metal milling unit, colored with Colour Liquid Prettau® Aquarell and sintered. We layered the structures with ceramic in the gingival area and on the vestibular sides of the anterior teeth, then we stained and glazed them. Once these steps were concluded, the final restoration was completed with titanium bases anodized in gingiva color and then screwed into the patient’s mouth.

PRODUCTS

PlaneFinder®
Device used to detect the Natural Head Position (NHP) as well as the occlusal plane angle
Item number: SYAA0360

Face Hunter
Scanner for the photo-realistic 3D digitization of faces as a working basis for the manufacture of individualized dental prostheses
Item number: SYAA0310

PSI Articulator
Physical and virtual articulator designed with special geometries to simulate patient-specific opening, sliding and closing movements of the jaw as they occur during mastication
Item number: SYAA0350

PlanePositioner®
Platform used to position the maxillary cast in the PSI articulator and to reproduce the occlusal plane
Item number: SYAA0370

JawPositioner (46 pieces)
With the PlanePositioner®, it allows to transfer into the laboratory articulator the digitally articulated models (maxilla)
Item number: ZBAC3501

JawPositioner Support
Support used to fix the JawPositioner into the orbit of the Zirkonzahn milling unit
Item number: ZBAC3511

ACCESSORIES

PlaneAnalyser
Instrument of analysis for recording and documenting the patient’s specific movements of the mandible (as well as for adjusting the articulator)
Item number: SYAA0370
Reference Transfer Plate
For the determination of the reference plane within the PlanePositioner®, in order to reference the maxilla in the PlaneAnalyzer®.

Bite Tray PlaneFinder® 1-3
Support made from sterilizable resin for the registration of the occlusion in the PlaneSystem®.

Item number: ZBAC2154

Bite Tray PlaneFinder® 2-4
Support made from sterilizable resin for the registration of the occlusion in the PlaneSystem® (larger size).

Item number: ZBAC2156

Spacers for Bite Tray PlaneFinder
Accessories used in cases of edentulism. In combination with the Bite Tray 1-3 and 2-4, they allow to register the height properly.

Item number: ZBAC2158

Positioning plates 5 mm
Plates used to set up the teeth on the PlanePositioner® (5 pieces).
Item number: ZBAC2353

Positioning plates 5 mm (separated)
Plates used to set up the teeth on the PlanePositioner® (6 pieces).
Item number: ZBAC2361

Set Bite Tray Face Hunter
5 supports for the positioning of the maxillary cast within the facial scans and 10 reference markers.

Item number: ZBAC2151

Flash for Face Hunter
5WRRQTVHQTƀ CUJGUHQTVJGHCEG*WPVGT
facial scanner

Item number: ZBAC1811

Set of inserts for the PSI articulator
Inserts for adjusting the surtrusion and the detrusion of the articulator.

Reference markers Bite Tray Face Hunter
10 stickers for the detection of the Bite Tray Face Hunter’s position.

Item number: ZBAC1811

Positioning plates 5 mm (separated)
Plates used to set up the teeth on the PlanePositioner® (6 pieces).
Item number: ZBAC2361

Flash for Face Hunter
Support for the face Hunter facial scanner equipped with a shelf for the laptop, height adjustable.

Item number: ZBAA4111

Tripod for Face Hunter
Support for the Face Hunter facial scanner, equipped with a shelf for the laptop, height adjustable.

Item number: ZBAA4111

Bite Tray PlaneFinder® 1-3
Support made from sterilizable resin for the registration of the occlusion in the PlaneSystem®.

Item number: ZBAC2154

Bite Tray PlaneFinder® 2-4
Support made from sterilizable resin for the registration of the occlusion in the PlaneSystem® (larger size).

Item number: ZBAC2156

Spacers for Bite Tray PlaneFinder
Accessories used in cases of edentulism. In combination with the Bite Tray 1-3 and 2-4, they allow to register the height properly.

Item number: ZBAC2158

Positioning plates 5 mm
Plates used to set up the teeth on the PlanePositioner® (5 pieces).
Item number: ZBAC2353

Positioning plates 5 mm (separated)
Plates used to set up the teeth on the PlanePositioner® (6 pieces).
Item number: ZBAC2361

Set Bite Tray Face Hunter
5 supports for the positioning of the maxillary cast within the facial scans and 10 reference markers.

Item number: ZBAC2151

Flash for Face Hunter
5WRRQTVHQTƀ CUJGUHQTVJGHCEG*WPVGT
facial scanner

Item number: ZBAC1811

Set of inserts for the PSI articulator
Inserts for adjusting the surtrusion and the detrusion of the articulator.
